A typical Motor Imagery (MI) experimental pipeline is composed of an EEG data acquisition phase, followed by an analysis phase to train a classification algorithm (such as LDA). The training uses features extracted from the acquired data such as spectral power for a subset of sensors and frequencies, in which desynchronization can be observed between the MI tasks.

The feature selection phase is crucial but can be a long step of trial-and-error, which is not acceptable in clinical settings. Training a classification algorithm can be challenging and time consuming as it may include multiple manipulations and datatype conversions with external softwares.

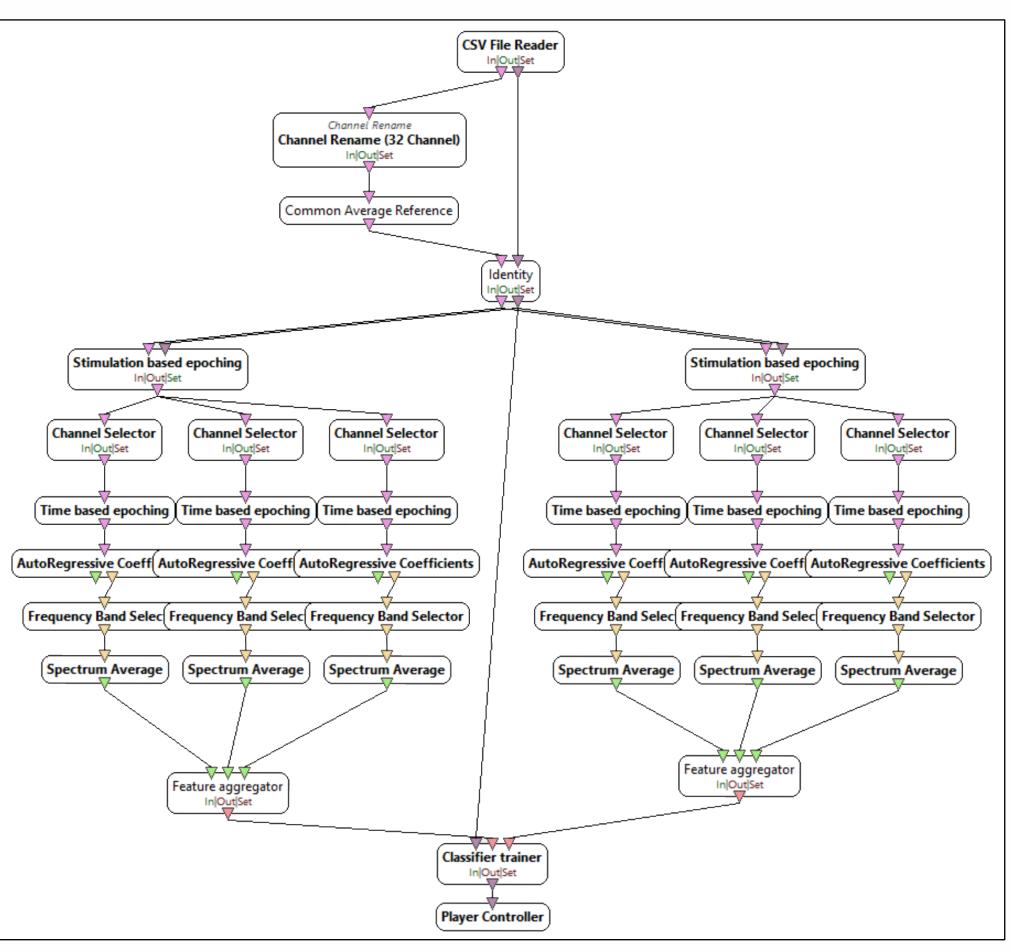

Here, we propose a new Python-based framework to manage the whole experimental pipeline smoothly, integrating seamlessly with OpenViBE.

Pipeline automation, simplified workflow

Pipeline setup: generation of scenarios and fine tuning of the acquisition step

- The experimental pipeline is set-up using templated scenarios, fine-tuned using pipeline-dependent parameters.
- This allows to provide a clean, controlled and risk-free working environment for non-technical clinician experimenters, removing the need for manually modifying OpenViBE scenario parameters.
- In the offline analysis & training steps, OpenViBE is used "in the background", hidden from the user, to make the experimental workflow as smooth and efficient as possible.
- Scenarios are modified on-the-fly, allowing to test various parameters (e.g., signal segmentation for spectral analysis, frequency resolution, channel of interest...) in a trial-and-error oriented workflow.
- We take advantage of the computational performance offered by OpenViBE, but we propose a framework which trades OV's flexibility and modularity for fixed, easy to manipulate scenarios.
- This framework was successfully validated using a Graz MI protocol with 2 classes, and an LDA classification algorithm with spectral power as discriminant feature.
- Integration of additional pipelines and methods is currently ongoing, following the same paradigm.

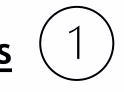

Training scenario: ex. of classifier training with 3 selected (channel; frequency band) spectral features

Key Features and Mechanisms

All offline capabilities (spectral feature extraction, visual analysis, classifier training) are available via a dashboard-like graphical interface.

Extraction of spectral features

- Runs of experimental data are displayed as they are recorded, and the user can choose during the acquisition phase of the experiment which signal(s) to analyse.
- This list can also be fed with pre-recorded signals, for analysis outside of the scope of an experiment.
- Extractions of spectral features useful for analysis, and of trials chunks for future training, are realized using OpenViBE in background, with scenarios automatically modified using pipelinedependent parameters.

View of the Feature Extraction Interface

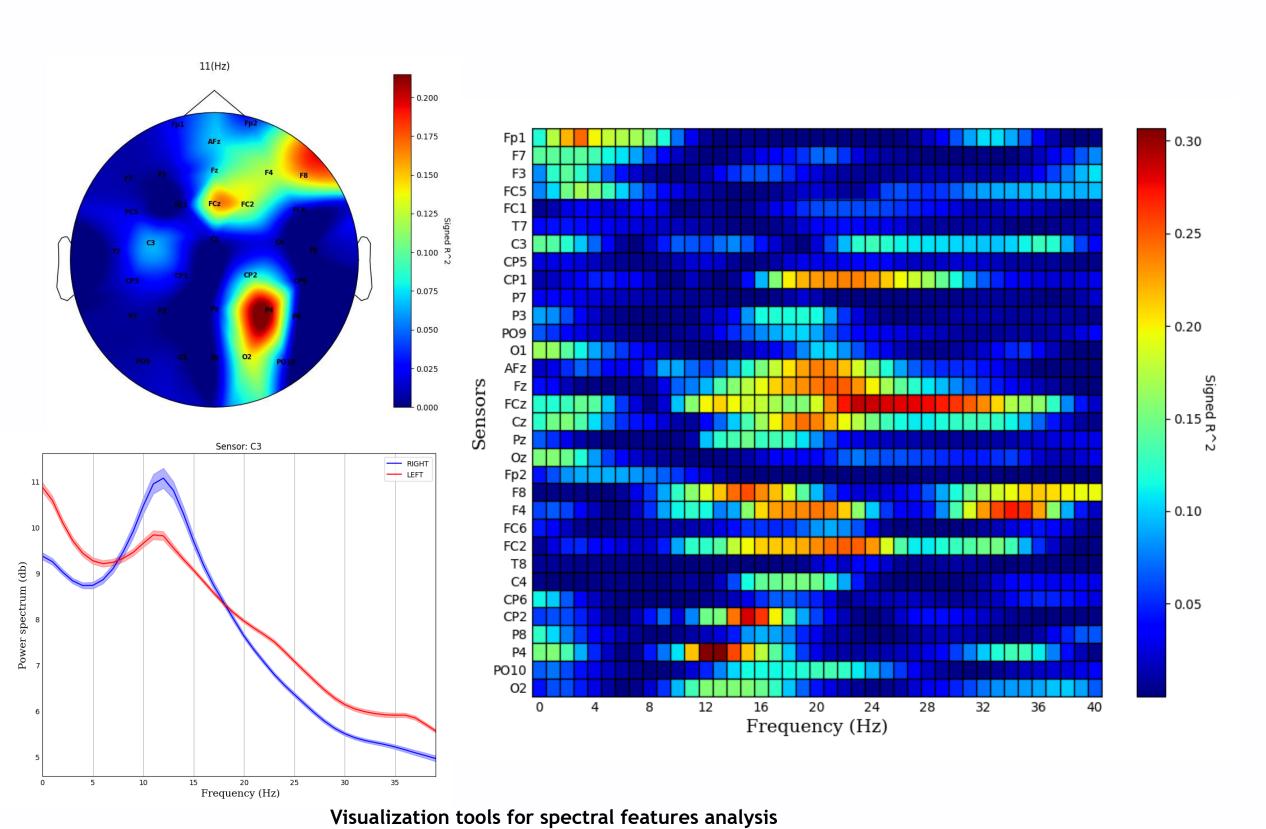

Visual analysis of spectral features

The classification algorithm is trained using a subset of sensors and frequency bands in which desynchronization can be observed between Motor Imagery tasks.

This selection is made easier through the use of visualization tools, allowing to display:

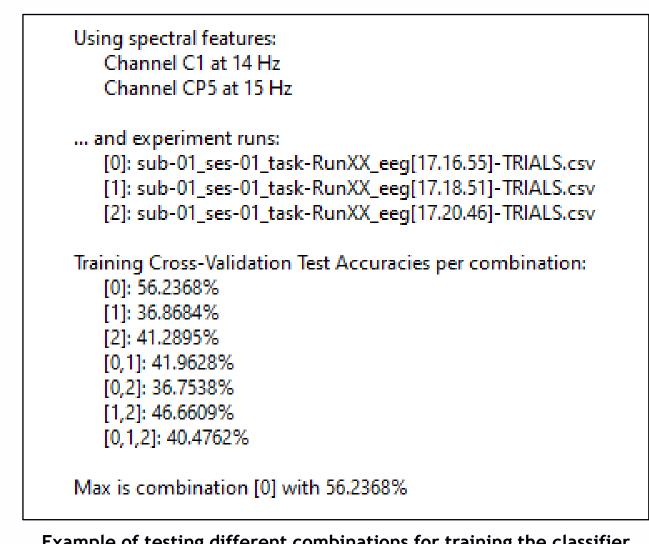

- frequency/channel map of R² values between the two tested conditions
- « brain topography » of R² values mapped on a scalp
- compared PSDs for the two conditions, for a given channel
- time/frequency ERD/ERS analysis, showing the difference in activity between baseline and task

Classifier training, trials combinations

- The classification algorithm can be trained with a few clicks. Here again, OpenViBE scenarios are run in the background after being automatically updated with entered values.
- This mechanism allows running various Multiple recorded training attempts. sessions can be selected, their trials being then concatenating.
- After training, the accuracy is displayed to user, and selected features and classifier weights are automatically updated in the "Online Testing" scenario, available directly without additional manipulation.
- A mechanism also allows for testing all possible combinations selected sessions, to determine the best possible combination.

Example of testing different combinations for training the classifier
